

Introduction

▼ Type	Lecture
📅 Date	@December 27, 2021
☰ Lecture #	1
🔗 Lecture URL	https://youtu.be/3a1FXBR6QXY
🔗 Notion URL	https://21f1003586.notion.site/Introduction-95ec26f2dc934c96a69762cad8582900
# Week #	1

Programming Languages

- A language is a medium for communication
- Programming languages communicate computational instructions
- Originally, directly connected to architecture
 - Memory locations store values, registers allow arithmetic
 - Load a value from memory location M into register R
 - Add the contents of the register R_1 and R_2 and store the result back in R_1
 - Write the value in R_1 to memory location M'
- Tedious and Error prone process

Abstraction

- Abstractions used in computational thinking
 - Assigning values to named variables
 - Conditional execution
 - Iteration
 - Functions/Procedures, recursion
 - Aggregate data structures — arrays, list, dictionaries
- Express such ideas in the programming language
 - Translate “high level” programming language to “low level” machine language
 - Compilers, interpreters

- Trade off expressiveness for efficiency
 - Less control over how code is mapped to the architecture
 - But fewer errors due to mismatch between intent and implementation

Styles of programming

- Imperative vs Declarative
- Imperative
 - How to compute
 - Step-by-step instructions on what is to be done
- Declarative
 - What the computation should produce
 - Often exploit inductive structures, express in terms of smaller computations
 - Typically avoid using intermediate variables
 - Combination of small transformations — functional programming

Imperative vs Declarative Programming, by example

- Add values in a list
- **Imperative** (in Python)

```
def sum_list(l):
    sum = 0
    for x in l:
        sum += x
    return sum
```

- Intermediate values `sum, x`
- Explicit iteration to examine each element in the list
- **Declarative** (in Python)

```
def sum_list(l):
    if l == []:
        return 0
    else:
        return l[0] + sum_list(l[1:])
```

- Describe the desired output by induction
 - Base case → Empty list has sum 0
 - Inductive step → Add the first element to the sum of the rest of the list
- No intermediate variables

-
- Sum of squares of even numbers upto `n`
 - **Imperative** (in Python)

```
def sum_square_even(n):
    sum = 0
    for x in range(n + 1):
        if x % 2 == 0:
            sum += x * x
    return sum
```

- We can code functionally in an imperative language
- Helps us identify natural units of (reusable) code
- **Declarative** (in Python)

```
def even(x):
    return x % 2 == 0

def square(x):
    return x * x

def sum_square_even(n):
    return sum(map(square, filter(even, range(n + 1))))
```

Names, types and values

- Internally, everything is stored as a sequence of bits
- No difference between data and instructions, let alone numbers, characters, booleans
 - For a compiler or interpreter, our code is its data
- We impose a notion of type to create some discipline
 - Interpret bit strings as "high level" concepts
 - Nature and range of allowed values
 - Operations that are permitted on these values
- Strict type-checking helps catch bugs early
 - Incorrect expression evaluation — like dimension mismatch in science
 - Incorrect assignment — expression value does not match variable type

Abstract datatypes, object-oriented programming

- Collections are important
 - Arrays, lists, dictionaries
- Abstract data types
 - Structured collection with fixed interface
 - Stack, for example, is a sequence but only allows `push` and `pop`
 - Separate implementation from interface
 - Priority queue allows `insert` and `delete-max`
 - Can implement a priority queues using sorted or unsorted lists, or using a heap
- Object-Oriented Programming
 - Focus on data types
 - Functions are invoked through the object rather than passing data to the functions
 - In python, `my_list.sort()` vs `sorted(my_list)`

What is yet to come ...

- Explore concepts in programming languages
 - Object-oriented programming
 - Exception handling, concurrency, event-driven programming
- Use Java as the illustrative language
 - Imperative, object-oriented
 - Incorporates almost all the features
- Discuss design decisions where relevant
 - Every language makes some compromises
- Understand and appreciate why there is a zoo of programming languages out there, *lol*
- And why new ones are still being created

Types

▼ Type	Lecture
📅 Date	@December 27, 2021
☰ Lecture #	2
🔗 Lecture URL	https://youtu.be/0GI9ygUk4K8
🔗 Notion URL	https://21f1003586.notion.site/Types-e3dd9b780c9d410086c44c63bffb6356
# Week #	1

The role of types

- Interpreting data stored in binary in a consistent manner
 - View sequence of bits as integers, floats, characters, ...
 - Nature and range of allowed values
 - Operations that are permitted on these values
- Naming concepts and structuring our computation
 - Especially at a higher level
 - `Point` VS `(Float, Float)`
 - Banking applications → accounts of different types, customers, ...
- Catching bugs early
 - Incorrect expression evaluation
 - Incorrect assignment

Dynamic vs Static Typing

- Every variable we use has a type
- How is the type of a variable determined
- Python determines the type based on the current value
 - **Dynamic typing** → derive type from the current value
 - `x = 10` — `x` is of type `int`
 - `x = 7.5` — now `x` is of type `float`

- An uninitialized name has no type
- **Static typing** → associate a type in advance with a name
 - Need to declare names and their types in advance
 - `int x, float a, ...`
 - Cannot assign an incompatible value — `x = 7.5` is illegal

- It is difficult to catch errors, such as typos

```
def factors(n):
    factorlist = []
    for i in range(1, n + 1):
        if n % i == 0:
            factorlst = factorlist + [i] # Typo here!
    return factorlist
```

- Empty user defined objects
 - Linked list is sequence of objects of type `Node`
 - Convenient to represent empty linked list by `None`
 - Without declaring type of `l`, Python cannot associate type after `l = None`

Types of organizing concepts

- Even simple type “synonyms” can help clarify code
 - 2D point is a pair `(float, float)`, 3D point is triple `(float, float, float)`
 - Create new type names `point2d` and `point3d`
 - These are synonyms for `(float, float)` and `(float, float, float)`
 - Makes the intent more transparent when writing, reading and maintaining code
- More elaborate types — abstract datatypes and object-oriented programming
 - Consider a banking application
 - Data and operations related to accounts, customers, deposits, withdrawals, transfers
 - Denote accounts and customers as separate types
 - Deposits, withdrawals, transfers can be applied to accounts, not to customers
 - Updating personal details applies to customers, not accounts

Static analysis

- Identify errors as early as possible — saves cost & effort
- In general, compilers cannot check that a program will work correctly
 - Halting problem — Alan Turing
- With variable declarations, compilers can detect type errors at compile time - **static analysis**
 - Dynamic typing would catch these errors only when the code runs
 - Executing code also shows down due to simultaneous monitoring for type correctness
- Compilers can also perform optimizations based on static analysis
 - Re-order statements to optimize reads and writes
 - Store previously computed expressions to re-use later

Summary

- Types have many uses
 - Making sense of arbitrary bit sequences in memory
 - Organizing concepts in our code in a meaningful way
 - Helping compilers catch bugs early, optimize compiled code

- Some languages also support automatic type inference
 - Deduce the types of variable statically, based on the context in which they are used
 - `x = 7` followed by `y = x + 15` implies `y` must be `int`
 - If the inferred type is consistent across the program, everything will go fine

Memory Management

Type	Lecture
Date	@December 27, 2021
Lecture #	3
Lecture URL	https://youtu.be/b4nsGWXNm2c
Notion URL	https://21f1003586.notion.site/Memory-Management-bf48fedf690e4df5991b9b7e9b9e1480
Week #	1

Keeping track of variables

- Variables store intermediate values during computation
 - Typically these are local to a function
 - Can also refer to global variables outside the function
 - Dynamically created data, like nodes in a list
- Scope of a variable
 - When the variable is available for use
 - In the following code, the `x` in `f()` is not in scope withing call to `g()`

```
def f(l):
    ...
    for x in l:
        y = y + g(x)
    ...

def g(m):
    ...
    for x in range(m):
        ...
```

- Lifetime of a variable
 - How long the storage remains allocated
 - Above, the lifetime of `x` in `f()` is till `f()` exists
 - “Hole in the scope” — variable is alive but not in scope

Memory stack

- Each function needs storage for local variables
- Create **activation record** when function is called
- Activation record are stacked
 - Popped when function exits
 - **Control link** points to start of previous record
 - **Return value link** tells where to store result

Call `factorial(3)`
`factorial(3)` calls `factorial(2)`

- Scope of a variable
 - Variable in activation record at top of stack
 - Access global variables by following control links
- Lifetime of a variable
 - Storage allocated is still on the stack

Passing arguments to a function

- When a function is called, arguments are substituted for formal parameters

```
def f(a,l):
    ...
    ...
    x = 7
    myl = [8,9,10]
    f(x,myl)
    a = x
    l = myl
    ... code for f() ...
```

- Parameters are part of the activation record of the function
 - Values are populated on function call
 - Like having implicit assignment statements at the start of the function
- Two ways to initialize the parameters
 - **Call by value** → copy the value
 - Updating the value inside the function has not side effect
 - **Call by reference** → parameter points to same location as the argument
 - Can have side-effects
 - It can update the contents, but cannot change the reference itself

Heap

- Function that inserts a value in a linked list
 - Storage for new node allocated inside function
 - Node should persist after function exits
 - Cannot be allocated within activation record
- We need a separate storage for the persistent data
 - Dynamically allocated vs statically declared
 - Usually called the heap
 - Not the same as heap data structure
 - Conceptually, allocate heap storage from “opposite” end with respect to the stack

- Heap store outlives activation record
 - Access through some variable that is in scope

Managing heap storage

- On the stack, variables are deallocated when a function exits
- How do we return unused storage on the heap?
 - After deleting a node in a linked list, deleted node is now dead storage, unreachable
- Manual memory management
 - Programmer explicitly requests and returns heap storage
 - `p = malloc(...)` and `free(p)` in C language
 - Error-prone — memory leaks, invalid assignments
- Automatic garbage collection (Java, Python, ...)
 - Run-time environment checks and cleans up dead storage
 - Mark all storage that is reachable from program variables
 - Return all unmarked memory cells to free space
 - Convenience for programmer vs performance penalty

Summary

- Variables have **scope** and **lifetime**
 - Scope → whether the variable is available in the program

- Lifetime → whether the storage is still allocated
- Activation records for functions are maintained as a stack
 - Control link points to previous activation record
 - Return value link tells where to store results
- Heap is used to store dynamically allocated data
 - Outlives activation record of function that created the storage
 - Need to be careful about deallocating heap storage
 - Explicit deallocation vs automatic garbage collection

Abstraction and Modularity

Type	Lecture
Date	@December 27, 2021
Lecture #	4
Lecture URL	https://youtu.be/8ciDI5cUhS
Notion URL	https://21f1003586.notion.site/Abstraction-and-Modularity-d39c0b22b59a4238b7173fef6074ebdc
Week #	1

Stepwise Refinement

- Begin with a high level description of the task
- Refine the tasks into subtasks
- Further elaborate each subtask
- Subtasks can be coded by different people
- **Program refinement** — focus on code, not much change in data structures

```
begin
  print first thousand prime numbers
end
```

```
begin
  declare table p
  fill table p with first thousand primes
  print table p
end
```

```
begin
  integer array p[1:1000]
  for k from 1 through 1000
    make p[k] equal to the kth prime number
  for k from 1 through 1000
    print p[k]
```

Data refinement

- Banking application
 - Typical functions → `CreateAccount(), Deposit()/Withdraw(), PrintStatement()`
- How do we represent each amount?
 - Only need the current balance
 - Overall, an array of balance

- Refine `PrintStatement()` to include `PrintTransactions()`
 - Now we need to record transactions for each account
 - Data representation also changes
 - Cascading impact on other functions that operate on accounts

Modular software development

- Use refinement to divide the solution into components
- Build a prototype of each component to validate design
- Components are described in terms of
 - **Interfaces** — what is visible to other components, typically function calls
 - **Specification** — behaviour of the component, as visible through the interface
- Improve each component independently, preserving interface and specification
- Simplest example of a component → a function
 - **Interfaces** — function header, arguments and return type
 - **Specification** — intended input-output behaviour
- Main challenge → suitable language to write specifications
 - Balance abstraction and detail, should not be another programming language
 - Cannot algorithmically check that specification is met (halting problem!)

Programming language support for abstraction

- Control abstraction
 - Functions and procedures
 - Encapsulate a block of code, re-use in different contexts
- Data abstraction
 - Abstract Data Types (ADTs)
 - Set of values along with operations permitted on them
 - Internal representation should not be accessible
 - Interaction restricted to public interface
 - For example, when a stack is implemented as a list, we should not be able to observe or modify the internal elements
- Object-Oriented programming
 - Organize ADTs in a hierarchy
 - Implicit reuse of implementations — subtyping, inheritance

Summary

- Solving a complex task requires breaking it down into manageable components
 - **Top-down:** refine the tasks into subtasks
 - **Bottom-up:** combine simple building blocks
- Modular description of components
 - Interface and specification
 - Build prototype implementation to validate design
 - Reimplement the components independently preserving interface and specification
- Programming Language support for abstraction
 - Control flow: functions and procedures
 - Data: Abstract data types, object-oriented programming

Object-Oriented Programming

▼ Type	Lecture
📅 Date	@December 27, 2021
☰ Lecture #	5
🔗 Lecture URL	https://youtu.be/NmYcNMPUIzY
🔗 Notion URL	https://21f1003586.notion.site/Object-Oriented-Programming-3bb75c2bcc92484d96ff97ef71bffd9
# Week #	1

Objects

- An object is like an abstract datatype
 - Hidden data with set of public operations
 - All interactions through operations — messages, methods, member-functions ...
- Uniform way of encapsulating different combinations of data and functionality
 - An object can hold single integer — eg. a counter
 - An entire filesystem or database could be a single object
- Distinguishing features of object-oriented programming
 - **Abstraction**
 - **Subtyping**
 - **Dynamic lookup**
 - **Inheritance**

History of object-oriented programming

- Objects first introduced in Simula — simulation language, 1960s
- Event-based simulation follows a basic pattern
 - Maintain a queue of events to be simulated
 - Simulate the event at the head of the queue
 - Add all events it spawns to the queue
- **Challenges**

- Queue must be well-types, yet hold all types of events
- Use a generic simulation operation across different types of events
 - Avoid elaborate checking of cases

Abstraction

- Objects are similar to abstract datatypes
 - Public interface
 - Private implementation
 - Changing the implementation should not affect interactions with the object
- Data-centric view of programming
 - Focus on what data we need to maintain and manipulate
- Recall that stepwise refinement could affect both code and data
 - Tying methods to data makes this easier to coordinate
 - Refining data representation naturally tied to updating methods that operate on the data

Subtyping

- Recall the Simula event queue
 - A well-typed queue holds values of a fixed type
 - In practice, the queue holds different types of objects
 - How can this be reconciled?
- Arrange types in a hierarchy
 - A subtype is a specialization of a type
 - If `A` is a subtype of `B`, wherever an object of type `B` is needed, an object of type `A` can be used
 - Every object of type `A` is also an object of type `B`
 - Think subset — if $X \subseteq Y$, every $x \in X$ is also in Y
- If `f()` is a method in `B` and `A` is a subtype of `B`, every object of `A` also supports `f()`
 - Implementation of `f()` can be different in `A`

Dynamic Lookup

- Whether a method can be invoked on an object is a static property — type-checking
- How the method acts is a dynamic property of how the object is implemented
 - In the simulation queue, all events support a `simulate` method
 - The action triggered by the method depends on the type of event
 - In a graphics application, different types of objects to be rendered
 - Invoke using the same operation, each object “*knows*” how to render itself
- Different from **overloading**
 - Operation `+` is addition for `int` and `float`
 - Internal implementation is different, but choice is determined by static type
- Dynamic lookup
 - A variable `v` of type `B` can refer to an object of subtype `A`
 - Static type of `v` is `B`, but method implementation depends on runtime type `A`

Inheritance

- Re-use of implementations
- Example: different types of employees

- `Employee` objects store basic personal data, date of joining
- `Manager` objects can add functionality
 - Retain basic data of `Employee` objects
 - Additional fields and functions: date of promotion, seniority (in current role)
- Usually one hierarchy of types to capture both subtyping and inheritance
 - `A` can inherit from `B` iff `A` is a subtype of `B`
- Philosophically, however the two are different
 - Subtyping is a relationship of interfaces
 - Inheritance is a relationship of implementations

Subtyping vs Inheritance

- A `deque` is a double-ended queue
 - Supports `insert-front()`, `delete-front()`, `insert-rear()` and `delete-rear()`
- We can implement a stack or a queue using a deque
 - Stack: use only `insert-front()`, `delete-front()`
 - Queue: use only `insert-rear()`, `delete-front()`
- `Stack` and `Queue` inherit from `Deque` — reuse implementation
- But `Stack` and `Queue` are not subtypes of `Deque`
 - If `v` of type `Deque` points an object of type `Stack`, cannot invoke `insert-rear()`, `delete-rear()`
 - Similarly, no `insert-front()`, `delete-rear()` in `Queue`
- Interfaces of `Stack` and `Queue` are not compatible with `Deque`
 - In fact, `Deque` is a subtype of both `Stack` and `Queue`

Summary

- Objects are like abstract datatypes
- Uniform way of encapsulating different combinations of data and functionality
- Distinguishing features of object-oriented programming
 - Abstraction
 - Public interface, private implementation, like ADTs
 - Subtyping
 - Hierarchy of types, compatibility of interfaces
 - Dynamic lookup
 - Choice of method implementation is determined at runtime
 - Inheritance
 - Reuse of implementations

Classes and Objects

▼ Type	Lecture
📅 Date	@December 27, 2021
☰ Lecture #	6
🔗 Lecture URL	https://youtu.be/TJC0WhS6FNo
🔗 Notion URL	https://21f1003586.notion.site/Classes-and-Objects-a6d38f8b11b44c269cb11bb0eb209107
# Week #	1

Programming with Objects

- Objects are like abstract datatypes
 - Hidden data with set of public operations
 - All interactions through operations — methods ...
- **Class**
 - Template for a data type
 - How a data is stored
 - How public functions manipulate the data
- **Object**
 - Concrete instance of the above mentioned template
 - Each object maintains its separate copy of local data
 - Invoke methods on objects — Equivalent to “**send a message to the object**”

Example: 2D points

- A point has coordinates `(x, y)`
 - Each point object stores its own internal values `x` and `y` — these are called instance variables
 - For a point `p`, the local values are `p.x` and `p.y`
 - `self` is a special name referring to the current object — `self.x, self.y`
- When we create an object, we need to set it up
 - Implicitly call a constructor function with a fixed name

- In Python, constructor is called `__init__()`
- Parameters are used to set up internal values
- In Python, the first parameter is always `self`

```
class Point:
    def __init__(self, a=0, b=0):
        self.x = a
        self.y = b
```

Adding methods to a class

- Translation: shift a point by $(\Delta x, \Delta y)$
 - $(x, y) \mapsto (x + \Delta x, y + \Delta y)$
 - Update instance variables

```
# This will go inside the Point class
def translate(self, dx, dy):
    self.x += dx
    self.y += dy
```

- Distance from the origin
 - $d = \sqrt{x^2 + y^2}$
 - Does not update instance variables
 - state of object is unchanged

```
# This will go inside the Point class
def odistance(self):
    import math
    d = math.sqrt(self.x*self.x + self.y*self.y)
    return d
```

Changing the internal implementation

- Polar coordinates: (r, θ) , not (x, y)
 - $r = \sqrt{x^2 + y^2}$
 - $\theta = \tan^{-1}(y/x)$
- Distance from origin is just r

```
import math
class Point:
    def __init__(self, a=0, b=0):
        self.r = math.sqrt(a*a + b*b)
        if a == 0:
            self.theta = math.pi/2
        else:
            self.theta = math.atan(b/a)

    def odistance(self):
        return self.r
```

- Translation
 - Convert (r, θ) to (x, y)
 - $x = r \cos \theta, y = r \sin \theta$
 - Recompute r, θ from $(x + \Delta x, y + \Delta y)$
- Interface has not changed
 - User need not be aware whether representation is (x, y) or (r, θ)

```
def translate(self, dx, dy):
    x = self.r * math.cos(self.theta)
```

```

y = self.r * math.sin(self.theta)
x += dx
y += dy
self.r = math.sqrt(x*x + y*y)
if x == 0:
    self.theta = math.pi/2
else:
    self.theta = math.atan(y/x)

```

Abstraction

- Users of our code should not know whether `Point` uses `(x, y)` or `(r, theta)`
 - Interface remains identical, or should remain identical
 - Even constructor is the same
- Python allows direct access to instance variables from outside the class

```
p = Point(5, 7)
```

```
p.x = 4 # Point is now (4, 7)
```

- This defeats the purpose of abstraction
- Changing the internal implementation of `Point` can have impact on other code
 - Usually called breaking changes

```

class Point:
    def __init__(self, a=0, b=0):
        self.x=a
        self.y=b

```

```

class Point:
    def __init__(self, a=0, b=0):
        self.r = math.sqrt(a*a + b*b)
        if a==0:
            self.theta = math.pi/2
        else:
            self.theta = math.atan(b/a)

```

Subtyping and inheritance

- Define `Square` to be a subtype of `Rectangle`
 - Different constructor
 - Same instance variables

```

class Rectangle:
    def __init__(self, w=0, h=0):
        self.width = w
        self.height = h

    def area(self):
        return self.width * self.height

    def perimeter(self):
        return 2 * (self.width + self.height)

class Square(Rectangle):
    def __init__(self, s=0):
        self.width = s
        self.height = s

```

- The following code is legal

```
s = Square(5)
```

```
a = s.area()
```

```
p = s.perimeter()
```

- `Square` inherits definitions from `area()` and `perimeter()` from `Rectangle`

Subtyping and inheritance

- Can change the instance variable in `Square`
 - `self.side`

```
class Rectangle:
    def __init__(self, w=0, h=0):
        self.width = w
        self.height = h

    def area(self):
        return self.width * self.height

    def perimeter(self):
        return 2 * (self.width + self.height)

class Square(Rectangle):
    def __init__(self, s=0):
        self.side = s
```

- The following code gives a runtime error

```
s = Square(5)
a = s.area()
p = s.perimeter()
```

- `Square` inherits definitions of `area()` and `perimeter()` from `Rectangle`
- But `s.width` and `s.height` have NOT been defined
- Subtype is not forced to be an extension of the parent type

-
- Subclasses and parent class are usually developed separately
 - Implementor of `Rectangle` changes the instance variables

```
class Rectangle:
    def __init__(self, w=0, h=0):
        self.wd = w
        self.ht = h

    def area(self):
        return self.wd * self.ht

    def perimeter(self):
        return 2 * (self.wd + self.ht)

class Square(Rectangle):
    def __init__(self, s=0):
        self.width = s
        self.height = s
```

- The following code gives a runtime error

```
s = Square(5)
a = s.area()
p = s.perimeter()
```

- `Square` constructor sets `s.width` and `s.height`
- But the instance variable names have changed

-
- Need a mechanism to hide private implementation details
 - Declare component private or public
 - Working within privacy constraints
 - Instance variables `wd` and `ht` of `Rectangle` are private
 - How can the constructor for `Square` set these private variables?
 - `Square` does (and should) not know the names of the private instance variables
 - Need to have elaborate declarations
 - Type and visibility of variables
 - Static type checking catches errors early

Summary

- A class is a template describing the instance variables and methods for an abstract datatype

- An object is a concrete instance of a class
- We should separate the public interface from the private implementation
- Hierarchy of class to implement subtyping and inheritance
- A language like Python has no mechanism to enforce privacy etc.
 - Can illegally manipulate private instance variables
 - Can introduce inconsistencies between subtypes and parent types
- Use strong declarations to enforce privacy, types
 - Do not rely on programmer disciplines
 - Catch bugs early through type checking

A First Taste of Java

▼ Type	Lecture
📅 Date	@January 3, 2022
☰ Lecture #	1
🔗 Lecture URL	https://youtu.be/ULpvhw2hmSg
🔗 Notion URL	https://21f1003586.notion.site/A-First-Taste-of-Java-c8303394228e4344969df9d13f8c4bd0
# Week #	2

Getting Started

- In Python

```
print('hello, world')
```

- In C ...

```
#include <stdio.h>
main() {
    printf("hello, world\n");
}
```

- And then there is Java ...

```
public class helloworld {
    public static void main(String[] args) {
        System.out.println("hello, world");
    }
}
```

Why so complicated?

```
public class helloworld {
    public static void main(String[] args) {
        System.out.println("hello, world");
    }
}
```

- All code in Java lies within a class
 - No free floating functions, unlike Python and other languages
 - Modifier `public` specifies visibility
- How does the program start?
 - Fix a function name that will be called by default
 - From C, the convention is to call this function `main()`
- Need to specify input and output types for `main()`
 - The signature of `main()`
 - Input parameters is an array of strings
 - Command line arguments
 - No output, hence the `main` function has the return type `void`
- Visibility
 - Function has to be available to run from outside the class
 - Modifier `public`
- Availability
 - Functions defined inside classes are attached to the objects
 - How can we create an object before starting?
 - Modifier `static` — function that exists independent of dynamic creation of objects, *belongs to the class*
- The actual operation
 - `System` is a public class
 - `out` is a ***stream*** object defined in `System`
 - Like a file handle
 - Note that `out` must also be `static`
 - `println()` is a method associated with streams
 - Prints argument with a newline, like Python `print()`
 - Adds a newline character `\n` at the end of the statement
- Punctuation `{`, `}`, `;` to delimit the blocks, statements
 - Unlike layout and indentation in Python

Compiling and running Java code

- A Java program is a collection of classes
- Each class is defined in a separate file with the same name, with extension `.java`
 - Class `helloworld` in `helloworld.java`
- Java programs are usually interpreted on **Java Virtual Machine (JVM)**
 - JVM provides a uniform execution environment across OSes
 - Semantics of Java is defined in terms of JVM, OS-independent
 - It came with a slogan “Write once, run anywhere”
- `javac` compiles into JVM **bytecode**
 - `javac helloworld.java` creates bytecode file `helloworld.class`
- `java helloworld` interprets and runs bytecode in `helloworld.class`
- Note:
 - `javac` requires file extension `.java`
 - `java` should not be provided file extension `.class`

- `javac` automatically follows dependencies and compiles all the classes required
 - Sufficient to trigger compilation for class containing `main()`

Summary

- The syntax of Java is comparatively heavy
- Many modifiers — unavoidable overhead of object-oriented design
 - Visibility: `public` and `private`
 - Availability: all functions live inside objects, need to allow `static` definitions
 - Will see more modifiers as we go along
- Functions and variable types have to be declared in advance
- Java compiles into code for a virtual machine
 - JVM ensures uniform semantics across operating systems
 - Code is guaranteed to be portable

Basic Datatypes in Java

▼ Type	Lecture
📅 Date	@January 3, 2022
☰ Lecture #	2
🔗 Lecture URL	https://youtu.be/lwTdVsLxz04
🔗 Notion URL	https://21f1003586.notion.site/Basic-Datatypes-in-Java-3cfdcb7953c14d4890ccc104b8264b26
# Week #	2

Scalar Types

- In an object-oriented language, all data should be encapsulated as objects
- However, this is cumbersome
 - Useful to manipulate numeric values like conventional languages
- Java has 8 primitive datatypes
 - `int, long, short, byte`
 - `float, double`
 - `char`
 - `boolean`
- Size of each type is fixed by JVM
 - Does not depend on native architecture

Type	Size in bytes
int	4
long	8
short	2
byte	1
float	4
double	8
char	2
boolean	1

- 2-byte `char` for Unicode

Declarations, assigning values

- We declare variables before we use them

```
int x, y;
float y;
char c;
boolean b1;
```

- The assignment statement works as usual

```
int x, y;
x = 5;
y = 7;
```

- Characters are written with single-quotes (only)
 - Double quotes mark string

```
char c, d;
c = 'x';
d = '\u03C0'; // Greek pi, unicode
```

- Boolean constants are `true, false`

```
boolean b1, b2;
b1 = false;
b2 = true;
```

Initialization, constants

- Declarations can come anywhere

```
int x;
x = 10;
float y;
```

- Use this judiciously to retain readability

- Initialize at the time of declaration

```
int x = 10;
float y = 5.7;
```

- Modifier `final` marks as constant

```
final float pi = 3.1415927f;
pi = 22/7; // Flagged as error
```

Operators, shortcuts, type casting

- Arithmetic operators are the usual ones

- `+, -, *, /, %`

- No separate integer division operator `//`

- When both arguments are integer, `/` is integer division

```
float f = 22/7; // Value is 3.0
```

- Note implicit conversion from `int` to `float`
- No exponentiation operator, use `Math.pow()`
- `Math.pow(a, n)` returns a^n
- Special operators for incrementing and decrementing integers

```
int a = 0, b = 10;

a++; // Same as a = a + 1

b--; // Same as b = b - 1
```

- Shortcut for updating a variable

```
int a = 0, b = 10;

a += 7; // Same as a = a + 7

b *= 12; // Same as b = b * 12
```

Strings

- `String` is a built in class
- String constants enclosed in double quotes

```
String s = "Hello", t = "world";
```

- `+` is overloaded for string concatenation

```
String s = "Hello";

String t = "world";

String u = s + " " + t; // "Hello world"
```

- String are not arrays of characters
 - We cannot write the following

```
s[3] = 'p';

s[4] = '!';
```

- Instead, invoke method `substring` in class `String`

```
s = s.substring(0, 3) + "p!";
```

- If we change a `String`, we get a new object
 - Strings are immutable
 - After the update, `s` points to a new `String`
 - Java does automatic garbage collection

Arrays

- Arrays are also objects
- Typical declaration

```
int[] a;

a = new int[100];
```

or

```
int[] a = new int[100];
```

- `a.length` gives the size of `a`
 - Note, for `String`, it is a method `s.length()`
- Array indices run from `0` to `a.length - 1`
- Size of the array can vary
- Array constants: `{v1, v2, v3}`
- For example

```
int[] a;

int n;

n = 10;
```

```
a = new int[n];  
  
n = 20;  
  
a = new int[n];  
  
a = {2, 3, 5, 7, 11};
```

Summary

- Java allows scalar types, which are not objects
 - `int, long, short, byte, float, double, char, boolean`
- Declarations can include initializations
- Strings and arrays are objects

Control Flow in Java

▼ Type	Lecture
📅 Date	@January 3, 2022
☰ Lecture #	3
🔗 Lecture URL	https://youtu.be/ORHDEourhdo
🔗 Notion URL	https://21f1003586.notion.site/Control-Flow-in-Java-3a68f0e8e0fb49a9babfea919410dc68
# Week #	2

Control flow

- Program layout
 - Statements end with semi-colon ;
 - Blocks of statements delimited by braces
- Conditional execution
 - `if (condition) { ... } else { ... }`
- Conditional Loop
 - `while (condition) { ... }`
 - `do { ... } while (condition);`
- Iteration
 - Two kinds of `for`
- Multiway branching — `switch`

Conditional Execution

- `if (c) { ... } else { ... }`
 - `else` is optional
 - Condition must be in parentheses
 - If body is a single statement, braces are not needed
- No `elif`, unlike python
 - Indentation is not forced

- Just align `else if`
- Nested `if` is a single statement, no separate braces required
- No surprises
- Aside: No `def` for function definition

```
public class MyClass {
    ...
    public static int sign(int v) {
        if (v < 0)
            return(-1);
        else if (v > 0)
            return(1);
        else
            return(0);
    }
}
```

Conditional Loops

- `while (c) { ... }`
 - Condition must be in parentheses
 - If body is a single statement, braces are not needed

```
public class MyClass {
    ...
    public static int sumupto(int n) {
        int sum = 0;
        while (n > 0) {
            sum += n;
            n--;
        }
        return(sum);
    }
}
```

- `do { ... } while (c);`
 - Condition is checked at the end of the loop
 - At one iteration, even if the condition is false
 - Useful for interactive user-input

```
do {
    read input;
} while (input-condition);
```

```
public class MyClass {
    ...
    public static int sumupto(int n) {
        int sum = 0;
        int i = 0;
        do {
            sum += i;
            i++;
        } while (i <= n);
        return(sum);
    }
}
```

Iteration

- `for` loop is inherited from C language
- `for (init; cond; upd) { ... }`
 - `init` is initialization
 - `cond` is terminating condition
 - `upd` is loop update

- Intended use is

```
for (i = 0; i < n; ++i) { ... }
```

- Completely equivalent to

```
i = 0;
while (i < n) {
    i++;
}
```

- However, not a good style to write `for` instead of `while`
- Can define loop variable within loop
 - The scope of `i` is local to the loop
 - An instance of more general local scoping allowed in Java

Sample code

```
public class MyClass {
    ...
    public static int sumarray(int[] a) {
        int sum = 0;
        int n = a.length;
        int i;

        for(i = 0; i < n; ++i) {
            sum += a[i];
        }

        return(sum);
    }
}
```

Iterating over elements directly

- Java later introduced a `for` in the style of Python

```
for x in l:
    do something with x
```

- Again `for`, different syntax

```
for (type x : a) {
    do something with x;
}
```

- It appears that loop variable must be declared in local scope for this version of `for`

Sample code

```
public class MyClass {
    ...
    public static int sumarray(int[] a) {
        int sum = 0;
        int n = a.length;

        for(int v : a) {
            sum += v;
        }

        return(sum);
    }
}
```

Multiway branching

- `switch` selects between different options
- The default behaviour of `switch` is to "fall through" from one case to the next
 - Need to explicitly `break` out of switch

- `break` available for loops as well
- Options have to be constants
 - Cannot use conditional expressions
- Aside: here return type is `void`
 - Non-void return type requires an appropriate return value

Sample code

```
public static void printsign(int v) {  
    switch(v) {  
        case -1: {  
            System.out.println("Negative");  
            break;  
        }  
        case 1: {  
            System.out.println("Positive");  
            break;  
        }  
        case 0: {  
            System.out.println("Zero");  
            break;  
        }  
    }  
}
```

Summary

- Program layout: semi-colons, braces
- Conditional execution: `if, else`
- Conditional loops: `while, do-while`
- Iteration: two kinds of `for`
 - Local declaration of loop variable
- Multiway branching: `switch`
 - `break` to avoid falling through

Defining Classes and Objects in Java

Type	Lecture
Date	@January 3, 2022
Lecture #	4
Lecture URL	https://youtu.be/XB-PcJJpKXg
Notion URL	https://21f1003586.notion.site/Defining-Classes-and-Objects-in-Java-5064c2d02789467897f97abe6e60c846
Week #	2

Defining a class

- Definition block using `class`, with class name
 - Modifier `public` to indicate visibility
 - Java allows `public` to be omitted
 - Default visibility is public to `package`
 - Packages are administrative units of code
 - All classes defined in the same directory form part of the same package
- Instance variable
 - Each concrete object of type `Date` will have local copies of `date, month, year`
 - These are marked `private`
 - Can also have `public` instance variable, but breaks encapsulation

```
public class Date {  
    private int day, month, year;  
    ...  
}
```

Creating Object

- Declare type using class name
- `new` creates a new object

- How do we set the instance variables?
- We can add methods to update values
 - `this` is a reference to current object

```
public class Date {
    private int day, month, year;

    public void setDate(int d, int m, int y) {
        this.day = d;
        this.month = m;
        this.year = y;
    }
}

public void useDate() {
    Date d;
    d = new Date();
    ...
}
```

- We can omit `this` if reference is unambiguous
- What if we want to check the values?
 - Methods to read and report values
- Accessor and Mutator methods

```
public class Date {
    ...
    public int getDay() {
        return(day);
    }

    public int getMonth() {
        return(month);
    }

    public int getYear() {
        return(year);
    }
}
```

Initializing objects

- Would be good to set up an object when we create it
 - Combine `new Date()` and `setDate()`
- Constructors — special functions called when an object is created
 - Function with the same name as the class
 - `d = new Date(13, 8, 2015);`
- Constructors with different signatures
 - `d = new Date(13, 8);` sets `year` to `2021`
 - Java allows function overloading — same name, different signatures
 - Python: default (optional) arguments, no overloading

```
public class Date {
    private int day, month, year;

    public Date(int d, int m, int y) {
        day = d;
        month = m;
        year = y;
    }

    public Date(int d, int m) {
        day = d;
        month = m;
        year = 2021;
    }
}
```

Constructors ...

- A later constructor can call an earlier one using `this` keyword
- If no constructor is defined, Java provides a default constructor with empty arguments
 - `new Date()` would implicitly invoke this
 - Sets instance variables to sensible defaults
 - For instance, `int` variables set to `0`
 - Only valid if no constructor is defined
 - Otherwise, we need an explicit constructor without arguments

```
public class Date {
    private int day, month, year;

    public Date(int d, int m, int y) {
        day = d;
        month = m;
        year = y;
    }

    public Date(int d, int m) {
        this(d, m, 2021);
    }
}
```

Copy constructors

- Create a new object from an existing one
- Copy constructor takes an object of the same type as an argument
 - Copies the instance variables
 - Use object name to disambiguate which instance variables we are talking about
 - Note that private instance variables of argument are visible
- Shallow copy vs Deep copy
 - Want new object to be disjoint from the old one
 - If instance variable are objects, we may end up aliasing rather than copying

```
public class Date {
    private int day, month, year;

    public Date(Date d) {
        this.day = d.day;
        this.month = d.month;
        this.year = d.year;
    }

    public void useDate() {
        Date d1, d2;
        d1 = new Date(12, 4, 1954);
        d2 = new Date(d1);
    }
}
```

Summary

- A class defines a type
- Typically, instance variables are private, available through accessor and mutator methods
- We declare variables using the class name as type
- Use `new` to create an object
- Constructor is called implicitly to set up an object
 - Multiple constructors — overloading
 - Re-use — one constructor can call another

- Default constructor — if none is defined
- Copy constructor — make a copy of an existing object

Basic Input and Output in Java

Type	Lecture
Date	@January 3, 2022
Lecture #	5
Lecture URL	https://youtu.be/zvtvQcUhFxo
Notion URL	https://21f1003586.notion.site/Basic-Input-and-Output-in-Java-9629c4bcf2de4676bf073f0997d4f87d
Week #	2

Interacting with a Java program

- We have seen how to print data
 - `System.out.println("Hello, world");`
- But how do we read data?

Reading input

- Simplest to use is the `Console` class
 - Functionality quite similar to Python `input()`
- Defined within `System`
 - Two methods, `readLine` and `readPassword`
 - `readPassword` does not echo characters on the screen
 - `readLine` returns a string (like Python `input()`)
 - `readPassword` returns an array of `char`

```
Console cons = System.console();
String username = cons.readLine("Username: ");
char[] password = cons.readPassword("Password: ");
```

- A more general `Scanner` class
 - Allows more granular reading of the input
 - Read a full line, or read an integer ...

```
Scanner in = new Scanner(System.in);
String name = in.nextLine();
int age = in.nextInt();
```

Generating Output

- `System.out.println(arg)` prints `arg` and goes to a new line
 - Implicitly converts argument to a string
- `System.out.print(arg)` is similar, but does not advance to a new line
- `System.out.printf(arg)` generates formatted output
 - Same conventions as `printf` in C language
